

Seeding systems for reliable crop establishment across Mallee soils

Trial Site Field Day, Murrayville, Tuesday 15 July 2014

The issue

MSF undertook an initial survey of 12 farmers in Murrayville region to identify what issues are perceived as limiting the success of crop establishment in Mallee soils and which aspects of district seeding systems need improvement. The survey was valuable in providing an insight into what seeding practices local farmers currently implement, what works well for them and what areas could be improved upon. The survey results showed that the greatest issue faced by most farmers was the inability to maintain a consistent and accurate seeding depth across all soil types in the paddock. As a result crop establishment is often variable with crops sown too shallow on the stony soils and too deep on the sandy soils which significantly impacts on crop emergence, especially canola. Unstable furrows filling in, residue handling limitations and poor soil/seed contact were other issues highlighted. Strong interest in seeding system solutions able to optimize the performance in stony soils and non-wetting sands – including disc and advanced tine technologies - was expressed by the majority of farmers.

The Trial

A 4 hectare demonstration trial was sown in May 2014 (6-9th) near Murrayville, showcasing eight different seeder set-up options (Table 1). The site is located in a typical Mallee paddock, comprising three soil types ranging from a heavy stony soil (swale) to a light sandy soil on the dune. Each plot was sown with a 6 row seeder on 11 inch row spacing and each plot is 205 m long and covers whole range of soils at the site (stony through to sandy). The plots were sown on a slight angle to the previous year's stubble and include 4 replications. A reference speed of 9km/h was used, reduced to 6.5km/h in stony areas, reflecting district practice.

Each seeding system is being evaluated in Clearfield wheat (Grenade, 37g/1000 grains) and canola (Pioneer 43C80, 4.1g/1000 seeds). The wheat was sown at 65 kg/ha targeting 160 plants/m² at 95% field establishment. The canola was sown at 2.5 kg/ha delivering 60 seeds/m². The wheat was treated with *Evergol Prime*TM fungicide and the Canola with *Gauche*TM insecticide + *Jockey*TM fungicide. Both crops were sown at the same targeted depth of 2cm, to allow a common assessment of seeding depth uniformity from the wheat plots.

Each crop had 65 kg/ha of Granulock Z 14 S (NPKS 20-13-0-7, 0.6% Zn) applied at seeding. The fertilizer was treated with *flutriafol (Intake*TM*)* fungicide. A further 110 kg/ha of a 60%/40% Urea/Ammonium Sulphate blend was applied across the site on the 3rd of July.

Prior to seeding a knockdown herbicide was applied across the entire site. *Sakura*TM herbicide was also applied prior to sowing on the wheat area only, however no pre emergent herbicide was applied to the canola plots. On the 3rd of July, the wheat was treated with 600 ml/ha of *Intervix*TM herbicide and the Canola was sprayed with 400 ml/ha of *Intervix*TM, 350 ml/ha of *Clethodim* and 75 ml/ha of *Haloxypop*. Both wheat and canola was treated with insecticides with 250 ml each of *Alpha cypermethrin* and *dimethoate* applied during herbicide application.

Treatments

The following seeding system treatments are included in the trial:

| Treatment Number | System description | System name | Opener | Fertiliser placement | Seed boot | Furrow closing |
|------------------|---------------------------------------|-------------------------|---------------------------------------|---|------------------------------------|----------------|
| 0 | District technology (Control) | Agmaster RB + narrow PW | 16mm knife point (Agmaster) | Fertiliser hose bracket (profile banding) | Adjustable rubber boot | 50mm wedge PW |
| 1 | Improved district technology | Agmaster + wide PW | 16mm knife point (Agmaster) | Fertiliser hose bracket (profile banding) | Adjustable rubber boot | 150mm wedge PW |
| 2 | Alternative chisel tyne technology 1 | Agmor + wide PW | 16mm knife point (Agmaster) | Fertiliser hose bracket (profile banding) | Adjustable Polyurethane Agmor UBV3 | 150mm wedge PW |
| 3 | Alternative chisel tyne technology 2a | RootBoot | 16mm knife point (RootBoot) | Shallow center banding | Paired row attachment | 110mm flat PW |
| 4 | Alternative chisel tyne technology 2b | Stealth | 30mm Stealth opener | Deep center banding | Paired row attachment | 110mm flat PW |
| 5 | Contour following technology 1 | Triple disc system | Yetter 24 wave fluted coulter | surface banding boot on coulter | K-Hart 3612 twin discs | PW 65mm |
| 6 | Contour following technology 2 | Seed Hawk | 14mm knife 1st opener | Deep banding front opener | Single row 2nd opener | PW 110mm |
| 7 | Hybrid technology: tyne + twin discs | Tyne/disc combo | 16mm Primary Sales knife point (PR87) | Primary Sales profile banding fertiliser boot | K-Hart 3612 twin discs | PW 65mm |

Note: PSA: Primary Sales Australia, PW: Press wheel

Data collection and results

The site is being intensively monitored for the impact of seeding system on crop establishment, seeding depth and crop productivity. Emergence counts on both wheat and canola plots, wheat seeding depth sampling have been conducted to date and rooting depth measurements will be taken over the duration of the season. Each 205m plot was subdivided into 12 subplots, each of 12m length, which will be individually assessed for soil characteristics (EM38, stoniness, texture) and crop response (NDVI), to help develop correlations between crop performance and soil factors. Yield data will be collected at harvest. Results of the trial will be available post-harvest and will be documented in the MSF Results Compendium.

Early results to date suggest the following:

- Good crop establishment in wheat (site average = 140 p/m² at 80% emergence) with few differences measured between seeding systems and a small influence of soil type with a trend for a small reduction in plant numbers in both stony soil and sand hills. (Fig. 1, Fig. 3)
- Fair crop establishment in canola (site average = 33 p/m² at 56% emergence) with higher losses observed across subplots (emergence varying between 35% and 84%) and larger differences between seeding systems (Fig. 2, Fig. 4). NOTE: The site has suffered significant seedling damage from insects
- Overall, a fair performance of the control system with no great differences in crop establishment highlighted between seeding systems, likely due to the wet conditions experienced following seeding (A trend of lower plant numbers is suggested for the disc and hybrid systems).
- Seeding depth data (based on emerged seedlings) varied across systems (18-35mm) despite the careful setting up at seeding. No clear interaction between canola emergence and seeding depth in this depth range. (Fig. 5)
- Seeding depth uniformity was best with disc seeding and Agmor system, and tended to be least with the higher disturbance paired row systems. (Fig. 6)

Acknowledgements

This project (Demonstrating Advanced Seeding Systems to Mallee Farmers) is supported with funding from the Australian Government. The project is also supported with funding from the Grains Research and Development Corporation (GRDC) project Maintaining Profitable Mallee Farming Systems with Retained Stubble.
